➢ Goal: Encode nodes → similarity in embedding space (dot product) ≈ similarity in the original graph

$$\underbrace{\text{similarity}(u, v)}_{\text{in the original network}} \approx \underbrace{\mathbf{z}_v^{\mathrm{T}} \mathbf{z}_u}_{\text{Similarity of the embedding}}$$

We need to define:
ENC(u)
Similarity(u, v)

ENC(u)

encode nodes

ENC(v)

$\mathbf{z}_u$

$\mathbf{z}_v$

original network   **embedding space**
- ➢ Given a graph and a starting point, we select a neighbour of it at random, and move to this neighbour

- ➢ Then, we select a neighbor of this point at random, and move to it,…

- ➢ The random sequence of nodes visited this way is **a random walk on the graph**
- ➤ Estimate probability of visiting node v on a random walk starting from node u using some random walk strategy R

- ➤ Optimize embeddings to encode these random walk statistics

$$\mathbf{z}_u^T \mathbf{z}_v \approx$$

$$P_R(v|u)$$
➢ Input: a text corpus $D = \{W\}$

➢ Output: $\boldsymbol{X} \in R^{|W| \times d}, d \ll |W|, d$-dim vector $\boldsymbol{X}_w$ for each word w
| Sentences | Word2vec | Latent representation vector |

➢ Geographically close words: a word and its context words -- in a sentence or document exhibit interrelations in human natural language

T. Mikolov, I Sutskever, K Chen, GS Corrado, J Dean. Distributed representations of words and phrases and their compositionality. In NIPS '13, pp. 3111-31119

➢ Input: a network $G = (V, E)$

➢ Output: $X \in R^{|V| \times d}, d \ll |V|, d$-dim vector X_v for each node V

Random walk paths (sentences)

Word2vec (Skip-gram)

Latent representation vector
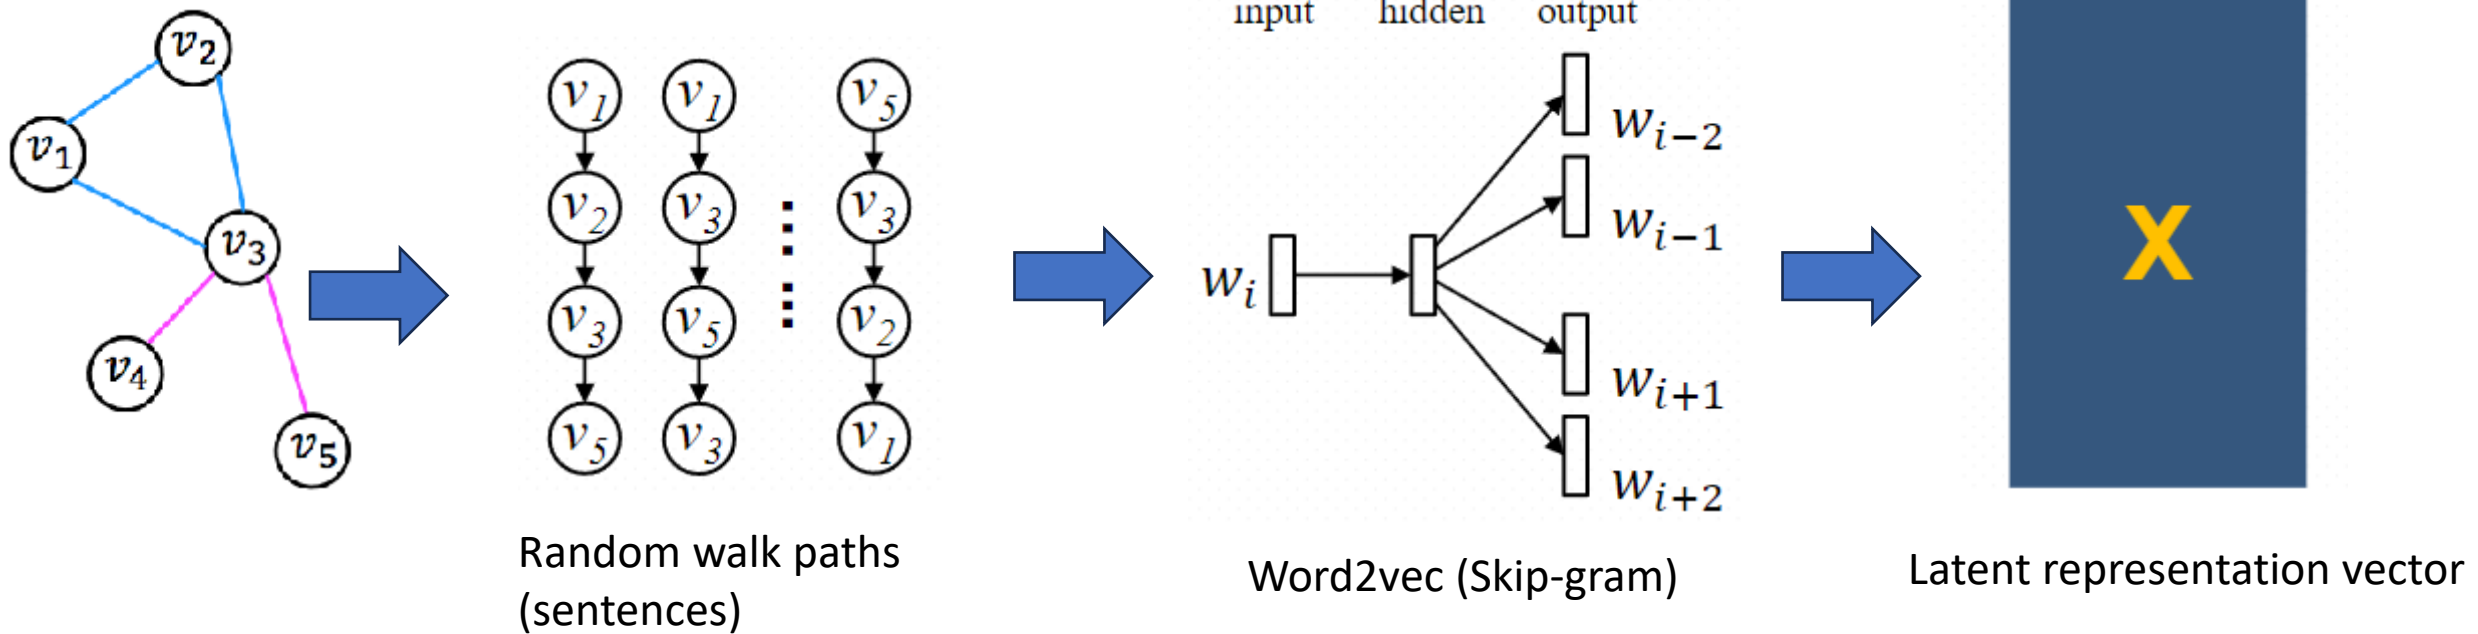

➢ Employ random walks on the graph to discover the structure

Bryan Perozzi et al: DeepWalk: Online Learning of Social Representations.

- ➢ Previous works are considering homogeneous network
  - ➢ Only one type of nodes and edges
  - ➢ Real world is ubiquitous
    - ➢ For example: social media websites like Facebook contain a set of node types, such as users, posts, groups, and tags
  - ➢ Special case of heterogeneous network
- ➢ Input: a heterogeneous information network $G = (V, E, T)$. T is object relation type
- ➢ Output: $X \in R^{|V| \times d}, d \ll |V|, d$-dim vector X_v for each node V
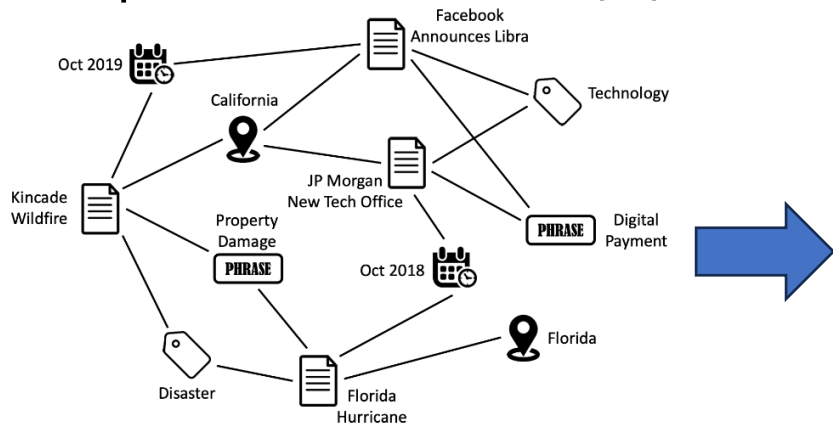

Latent representation vector

➢ How do we effectively preserve the concept of "node-context" among multiple types of nodes?

     ➢ E.g., users, posts, groups and, tags in social heterogeneous networks

     ➢ Or authors, papers, & venues in academic heterogeneous networks

➢ Can we directly apply homogeneous network embedding architectures to heterogeneous networks?

➢ It is also difficult for conventional meta-path-based methods to model similarities between nodes without connected meta-paths

- ➢ **Solution**: meta-path based random walk (inspired by DeepWalk and Node2Vec)

  - ➢ metapath2vec and metapath2vec++

- ➢ **Goal**: to generate paths that can capture both the semantic and structural correlations between different types of nodes, facilitating the transformation of heterogeneous network structures into skip-gram
Heterogenous network   Skip-gram in metapath2vec   Skip-gram in metapath2vec++
Yuxiao Dong et al:"metapath2vec: Scalable representation learning for heterogeneous networks." *Proceedings of the 23rd ACM SIGKDD international conference on knowledge discovery and data mining*, 2017.
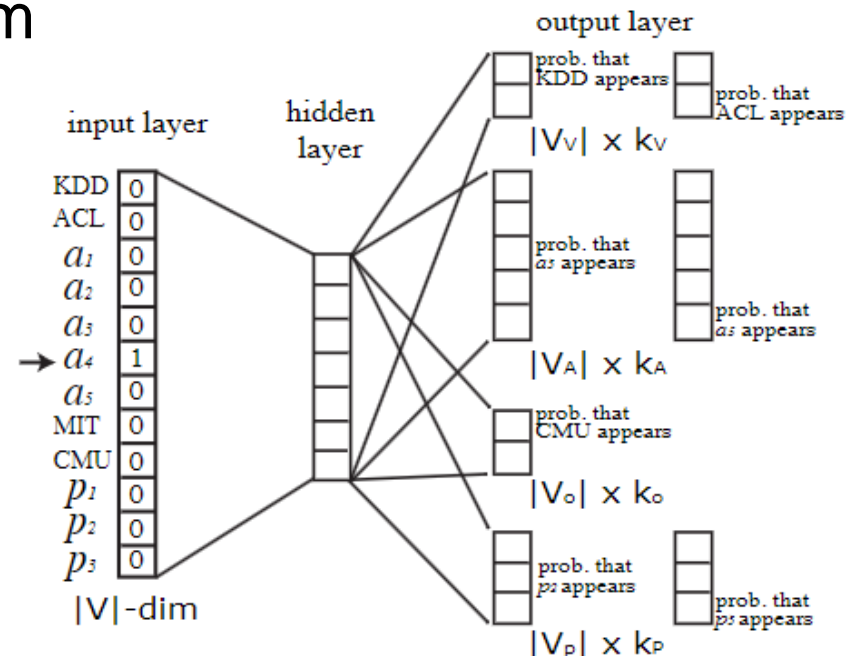

➢ Network schema $S = (V, R)$ of graph G

  ➢ Directed graph defined over node types V and with edges as relations from R

➢ meta-path: based on network schema S

  ➢ Denoted as $V_1 \xrightarrow{R_1} V_2 \xrightarrow{R_2} \cdots V_t \xrightarrow{R_t} V_{t+1} \cdots \xrightarrow{R_{l-1}} V_l$

  ➢ Node types $V_1, V_2, \ldots, V_l \in V$ and edge type $R_1, R_2, \ldots, R_{l-1} \in R$

APA

APCPA
➢ Each meta-path captures the proximity between the nodes on its two ends from a particular semantic perspective

➤ Given a meta-path scheme:

$$V_1 \xrightarrow{R_1} V_2 \xrightarrow{R_2} \cdots V_t \xrightarrow{R_t} V_{t+1} \cdots \xrightarrow{R_{l-1}} V_l$$

➤ The transition probability at step i is defined as:

$$p(v^{i+1}|v_t^i, \mathcal{P}) = \begin{cases} \frac{1}{|N_{t+1}(v_t^i)|} & (v^{i+1}, v_t^i) \in E, \phi(v^{i+1}) = t+1 \\ 0 & (v^{i+1}, v_t^i) \in E, \phi(v^{i+1}) \neq t+1 \\ 0 & (v^{i+1}, v_t^i) \notin E \end{cases}$$

➤ Recursive guidance for random walkers, i.e.,

$$p(v^{i+1}|v_t^i) = p(v^{i+1}|v_1^i), \text{ if } t = l$$

Yuxiao Dong et al:"metapath2vec: Scalable representation learning for heterogeneous networks." *Proceedings of the 23rd ACM SIGKDD international conference on knowledge discovery and data mining*, 2017.
➢ Given a meta-path scheme (Example):

OAPVPAO

➢ In a traditional random walk procedure, the next step of a walker on node a4 transitioned from node CMU can be all types of nodes surrounding it - a2,a3, a5, p2, p3, and CMU

➢ Under the meta-path scheme 'OAPVPAO', for example, the walker is biased towards paper nodes (P) given its previous step on an organization node CMU (O), following the semantics of this meta-path

Yuxiao Dong et al:"metapath2vec: Scalable representation learning for heterogeneous networks." *Proceedings of the 23rd ACM SIGKDD international conference on knowledge discovery and data mining*, 2017.
➢ **Softmax in Metapath2Vec**

$$p(c_t | v; \theta) = \frac{e^{X_{c_t} \cdot X_v}}{\sum_{u \in V} e^{X_u \cdot X_v}},$$

→ **Not consider node type**

➢ **The potential issue of skip-gram for heterogeneous network embedding:**

   ➢ Predict the context node c_t (type t) given a node v, metapath2vec encourages all types of nodes to appear in this context position

Yuxiao Dong et al:"metapath2vec: Scalable representation learning for heterogeneous networks." *Proceedings of the 23rd ACM SIGKDD international conference on knowledge discovery and data mining*, 2017.
➢ **Metapath2Vec++**: Heterogeneous Skip-Gram

➢ Objective function (heterogeneous negative sampling):

$$O(\mathbf{X}) = \log \sigma(X_{c_t} \cdot X_v) + \sum_{m=1}^{M} \mathbb{E}_{u_t^m \sim P_t(u_t)}[\log \sigma(-X_{u_t^m} \cdot X_v)]$$

➢ Softmax in Metapath2Vec++

$$p(c_t | v; \theta) = \frac{e^{X_{c_t} \cdot X_v}}{\sum_{u_t \in V_t} e^{X_{u_t} \cdot X_v}}$$

Consider node type t

➢ Stochastic gradient descent

$$\frac{\partial O(\mathbf{X})}{\partial X_{u_t^m}} = (\sigma(X_{u_t^m} \cdot X_v - \mathbb{I}_{c_t}[u_t^m]))X_v$$

$$\frac{\partial O(\mathbf{X})}{\partial X_v} = \sum_{m=0}^{M} (\sigma(X_{u_t^m} \cdot X_v - \mathbb{I}_{c_t}[u_t^m]))X_{u_t^m}$$

Yuxiao Dong et al:"metapath2vec: Scalable representation learning for heterogeneous networks." *Proceedings of the 23rd ACM SIGKDD international conference on knowledge discovery and data mining*, 2017.
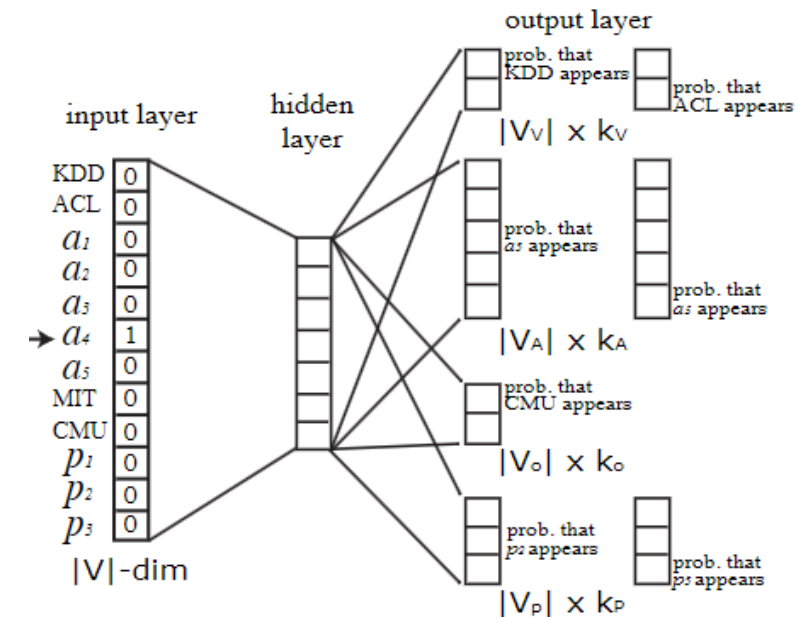

Input: The heterogeneous information network $G = (V, E, T)$, a meta-path scheme $\mathcal{P}$, #walks per node w, walk length l, embedding dimension d, neighborhood size k

Output: The latent node embeddings $\mathbf{X} \in \mathbb{R}^{|V| \times d}$

initialize $\mathbf{X}$;
for $i = 1 \rightarrow w$ **do**
    for $v \in V$ **do**
        $MP = \text{MetaPathRandomWalk}(G, \mathcal{P}, v, l)$;
        $\mathbf{X} = \text{HeterogeneousSkipGram}(\mathbf{X}, k, MP)$;
    end
end
return $\mathbf{X}$;

MetaPathRandomWalk$(G, \mathcal{P}, v, l)$
$MP[1] = v$;
for $i = 1 \rightarrow l-1$ **do**
    draw u according to Eq. 3 ;
    $MP[i+1] = u$;
end
return MP ;

HeterogeneousSkipGram$(\mathbf{X}, k, MP)$
for $i = 1 \rightarrow l$ **do**
    $v = MP[i]$;
    for $j = max(0, i-k) \rightarrow min(i+k, l) \, \& \, j \neq i$ **do**
        $c_t = MP[j]$;
        $\mathbf{X}^{new} = \mathbf{X}^{old} - \eta \cdot \frac{\partial O(\mathbf{X})}{\partial \mathbf{X}}$ (Eq. 7) ;
    end
end

➢ Every sub-procedure is easy to parallelize

➢ 24-32X speedup by using 40 cores

Metapath2Vec
➢ Meta-paths must be manually customized based on task and dataset, hence requiring domain knowledge

➢ They fail to capture more complex relationships such as motifs, i.e. patterns of interconnections occurring in complex networks at numbers that are significantly higher than those in randomized networks

➢ The usage of meta-path is limited to the discrete space. So, if two vertices are not structurally connected in the graph, metapath-based methods cannot capture their relations

➢ **Solution**: propose JUST, which performs random walks by probabilistically deciding whether to "jump" to a different node type or "stay" in the same node type

  ➢ No rely on predefined meta-paths

  ➢ **Balance** between **homogeneous** edges (same node type) and **heterogeneous** edges (across node types)

  ➢ balances the node distribution over different node types by controlling the jumping behavior
➢ Perform random walks on the heterogeneous graph, but probabilistically decide at each step

  ➢ **Jump** to a target domain q: uniformly sampling one node from those in a target domain q connected to v_i via heterogeneous edge

$$V^q_{jump}(v_i) = \{v | (v_i, v) \in E_{he} \vee (v_i, v) \in E_{he}, \phi(v) = q\}$$

  ➢ **Stay** in the current domain: uniformly sampling one node from those connected to vi via homogeneous edges

$$V_{stay}(v_i) = \{v | (v_i, v) \in E_{ho} \vee (v_i, v) \in E_{ho}\}$$

➢ **Probability** for stay or jump is controlled by an exponential decay function:

➢ Stay:

$$Pr_{stay}(v_i) = \begin{cases} 0, & \text{if } V_{stay}(v_i) = \emptyset \\ 1, & \text{if } \{V_{jump}^q(v_i) | q \in Q, q \neq \phi(v_i)\} = \emptyset \\ \alpha^l, & \text{otherwise} \end{cases}$$

➢ Jump:

$$Q_{Jump}(v_i) = \begin{cases} \{q | q \in Q \wedge q \notin Q_{hist}, V_{jump}^q(v_i) \neq \emptyset\}, & \text{if not empty} \\ \{q | q \in Q, q \neq \phi(v_i), V_{jump}^q(v_i) \neq \emptyset\}, & \text{otherwise} \end{cases}$$
Algorithm 1 Truncated Random Walk with Jump & Stay

Require: A heterogeneous graph $G = (V, E)$, initial stay probability α, number of memorized domains m, number of random walks per node r, maximum walk length L_{max}

1: Initialize an empty set of walks $\mathcal{W} = \emptyset$
2: **for** $i = 1$ to r **do**
3:     **for** each $v \in V$ **do**
4:         Initialize a random walk by adding v;
5:         Initialize Q_{hist} by adding $\phi(v)$;
6:         **while** $|W| < L_{max}$ **do**
7:             Pick a Jump or Stay decision according to Eq. 1;
8:             **if** Stay **then**
9:                 Continue W by staying;
10:             **else if** Jump **then**
11:                 Sample a target domain q from Eq. 2;
12:                 Continue W by jumping to domain q;
13:                 Update Q_{hist} by keeping only last m domains;
14:             **end if**
15:         **end while**
16:         Add W to $\mathcal{W}$
17:     **end for**
18: **end for**
19: **return** The set of random walks $\mathcal{W}$

➢ Apply Skip-gram model same as metapth2vec

➢ Different with Metapath2Vec:

    ➢ Decide probabilistically whether to "jump" across node types via a heterogeneous edge or "stay" in the same node type via a homogeneous edge

    ➢ When jumping, select the target node type probabilistically while trying to avoid recently visited node types

Rana Hussein et al:"Are Meta-Paths Necessary? Revisiting Heterogeneous Graph Embeddings."

네트워크 과학 연구실 NETWORK SCIENCE LAB   가톨릭대학교 THE CATHOLIC UNIVERSITY OF KOREA

- ➢ **Motivation**: Random walk produces an imbalanced training of heterogeneous networks

  - ➢ The major relation types take a large portion of training samples

  - ➢ Dominate the training and minor relation types will hardly be learned

- ➢ **Idea**: Formulate heterogeneous network embedding as a multi-task learning problem, where each task corresponds to a relation type in the network.

  - ➢ Allow handling the imbalance by focusing on under-trained relation types

- ➢ **Solution**: Introduce an inverse training ratio tensor that quantifies how well each relation type is represented in the embedding space based on the task losses

  - ➢ Propose a biased random walk strategy that uses the inverse training ratios to generate walks containing more of the under-trained relation types

네트워크 과학 연구실
NS NETWORK SCIENCE LAB

가톨릭대학교
THE CATHOLIC UNIVERSITY OF KOREA

- ➢ **Biased random walk generator**:

  - ➢ Determine the type for the next node by sampling and do another sampling for the next node that has the sampled type

- ➢ A stochastic matrix to store transition probabilities between node types

$$P_{ij} = p\left(t_j|t_i\right) \text{ such that } \sum_i P_{ij} = 1$$

- ➢ For k steps:

$$(P^k)_{ij} = p\left(t_j|t_i, k\right)$$

- ➢ **From inverse training ratio tensor to stochastic matrix**:

    - ➢ Sample more of less-trained relations so that the less-trained relations would be reflected more in the embedding space

- ➢ Perturbation approach with uniform probability:

$$P_{uni_{xy}} = \begin{cases} \frac{1}{degree(t_x)} & \text{if } (t_x, t_y) \in E_{meta} \\ 0 & \text{otherwise} \end{cases}$$

- ➢ Probability to move from t_i to t_j in k steps

Perturbation parameter

$$L_{stochastic} = \sum_{i=0}^{k-1} \left| P^{i+1} - \left(P_{uni}^{i+1} + \alpha \left(I_i - 1 \right) \right) \right|_F^2$$

- ➢ Update stochastic matrix: update nonzero values and clip the values between zero and one

    - ➢ Preserve the property in the stochastic matrix

➢ **Skip-gram model**: Learn embedding table Q where $f(v_i) = Q[i]$

➢ The skip-gram loss for one random walk w

$$L = -\sum_{i=1}^{l}\sum_{j=1}^{k} \log p\left(w_{i+j} \mid w_i\right) = -\sum_{i=1}^{l}\sum_{j=1}^{k} \log \frac{e^{f(w_{i+j})^{\top}f(w_i)}}{\sum_{v_n}^{V} e^{f(v_n)^{\top}f(w_i)}}.$$

Negative log-likelihood (Softmax function)

Take m samples ⟹

$$L = -\sum_{i=1}^{l}\sum_{j=1}^{k}\left(L_p\left(w_{i+j}, w_i\right) + \sum_{v_o}^{N_V} L_n\left(v_o, w_i\right)\right)$$

$$L_p\left(v_c, v_s\right) = \log \sigma\left(f(v_c)^{\top} f(v_s)\right)$$

$$L_n\left(v_c, v_s\right) = \log \sigma\left(-f(v_c)^{\top} f(v_s)\right),$$

Sigmoid function

➢ Multi-task setting: Possible task set is defined

$$\mathcal{J}_{possible} = \left\{ J_{xyz} \mid (A^z)_{xy} > 0 \right\}$$

A = the adjacency matrix of G_{meta}

➢ Balance in multitasks:

$$L\left[J_{xyz}\right] = -\frac{\sum_{i=1}^{l}\left(L\left[J_{xyz}\right]_{p}(w_{i+z+1}, w_{i}) + \sum_{v_o}^{N_v} L\left[J_{xyz}\right]_{n}(v_o, w_i)\right)}{\sum_{i=1}^{l}\left(\mathbb{I}\left[J_{xyz}\right](w_{i+z+1}, w_{i}) + \sum_{v_o}^{N_v} \mathbb{I}\left[J_{xyz}\right](v_o, w_i)\right)}$$

$$L\left[J_{xyz}\right]_{p}(v_c, v_s) = \begin{cases} L_p(v_c, v_s) & \text{if } \phi(v_c) = t_y \wedge \phi(v_s) = t_x \\ 0 & \text{otherwise} \end{cases}$$

$$L\left[J_{xyz}\right]_{n}(v_c, v_s) = \begin{cases} L_n(v_c, v_s) & \text{if } \phi(v_c) = t_y \wedge \phi(v_s) = t_x \\ 0 & \text{otherwise} \end{cases}$$

$$\mathbb{I}\left[J_{xyz}\right](v_c, v_s) = \begin{cases} 1 & \text{if } \phi(v_c) = t_y \wedge \phi(v_s) = t_x \\ 0 & \text{otherwise} \end{cases}$$

네트워크 과학 연구실 NETWORK SCIENCE LAB   가톨릭대학교 THE CATHOLIC UNIVERSITY OF KOREA

➢ The inverse training ratios (some relation types are not contained in a random walk by chance)

$$\tilde{L}\left[J_{xyz}\right](t) = L\left[J_{xyz}\right]/L_{initial}\left[J_{xyz}\right]$$

$$r\left[J_{xyz}\right](t) = \tilde{L}\left[J_{xyz}\right](t)/\mathbb{E}_{J_{possible}}\left[\tilde{L}\left[J\right](t)\right],$$

➢ The tasks that always not occur in a random walk

$$I_{zxy}(t) = \begin{cases} r[J_{xyz}](t) & \text{if } J_{xyz} \in J_{possible} \\ 1 & \text{otherwise} \end{cases}$$

➢ Heterogeneous skip-gram model: Sample negative nodes which have the same type with positive node

$$L_p(v_c, v_s) = \log \sigma\left(\left(\sqrt{r} \odot f(v_c)\right)^{\top}\left(\sqrt{r} \odot f(v_s)\right)\right)$$

$$L_n(v_c, v_s) = \log \sigma\left(-\left(\sqrt{r} \odot f(v_c)\right)^{\top}\left(\sqrt{r} \odot f(v_s)\right)\right)$$

$$r = f_R\left(k, \phi(v_c), \phi(v_s)\right)$$

Biased Random Walk   Skip-gram model
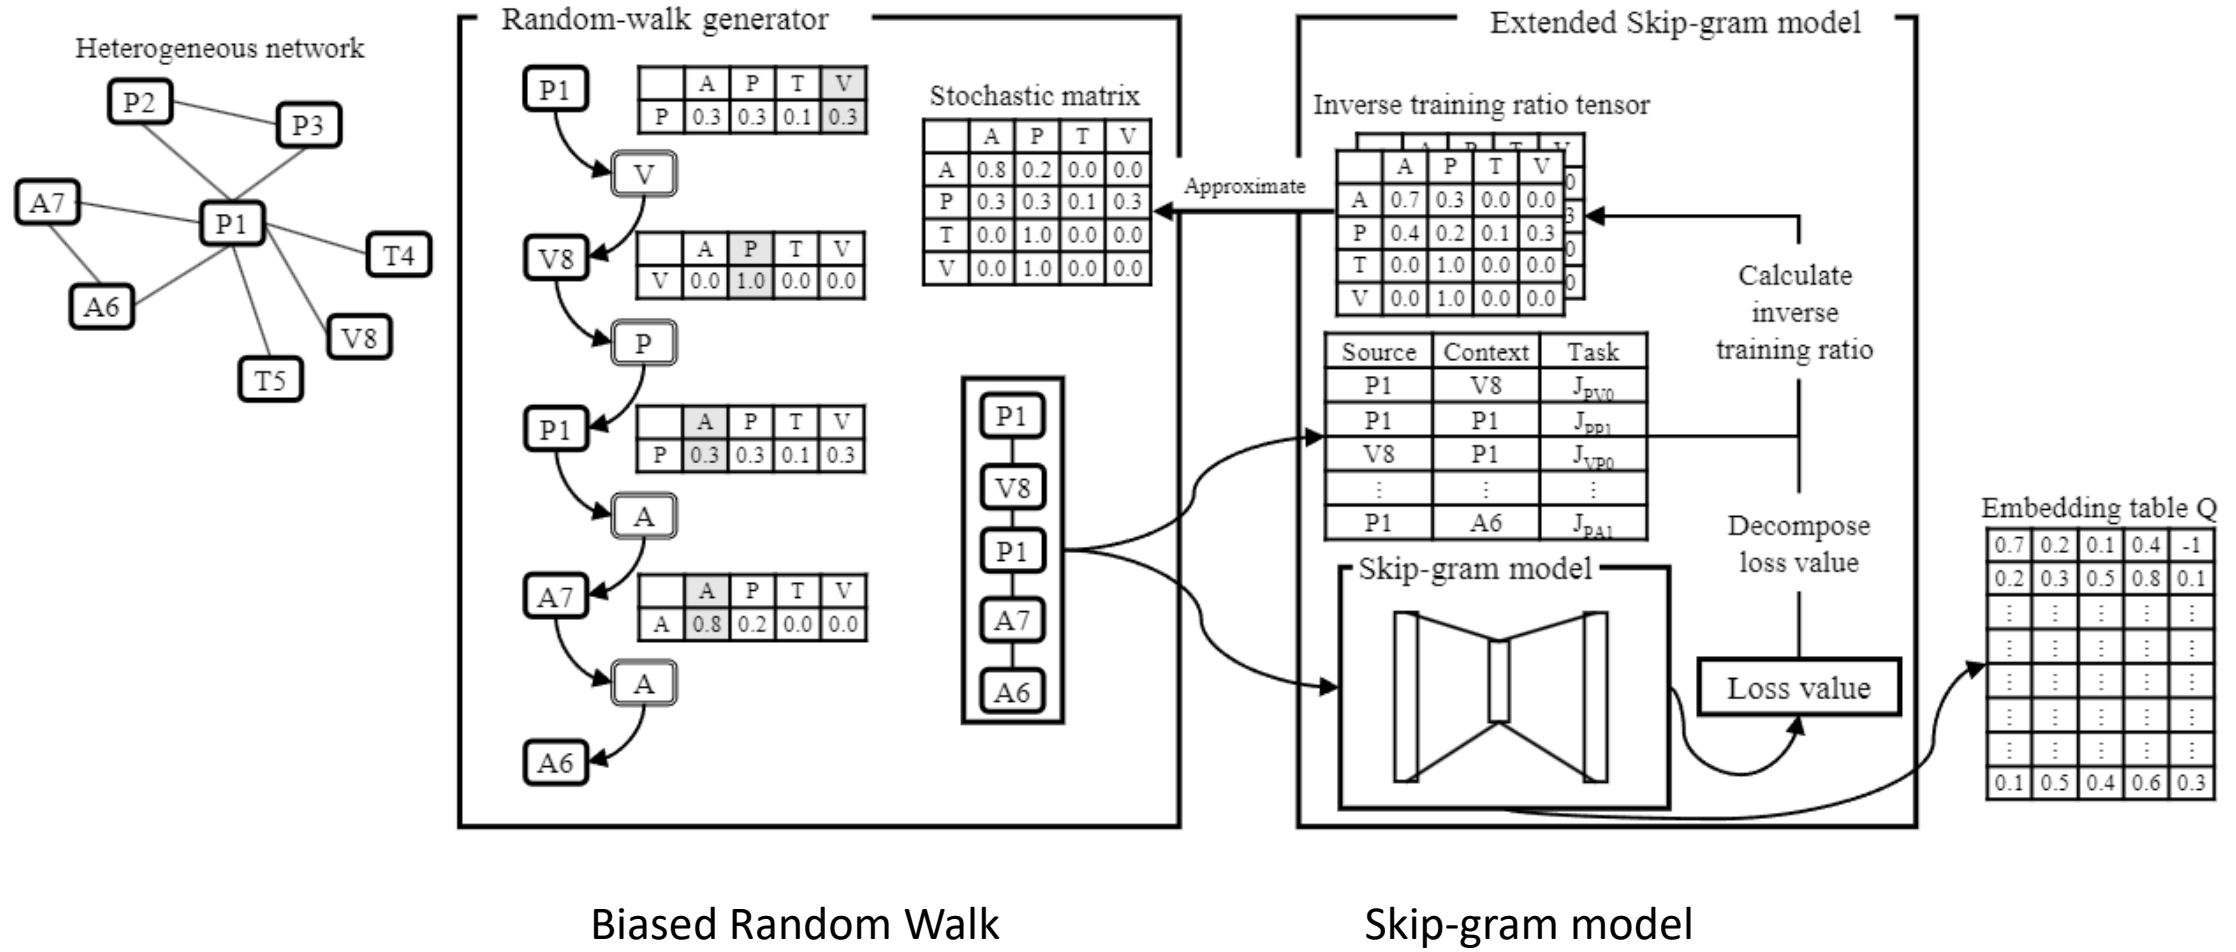

➢ Previous random walk methods – DeepWalk, Node2Vec, LINE, Struc2Vec, Metapath2Vec, etc – are relied on static graph

➢ However, the networks in the real world are dynamic

   ➢ Evolving over time
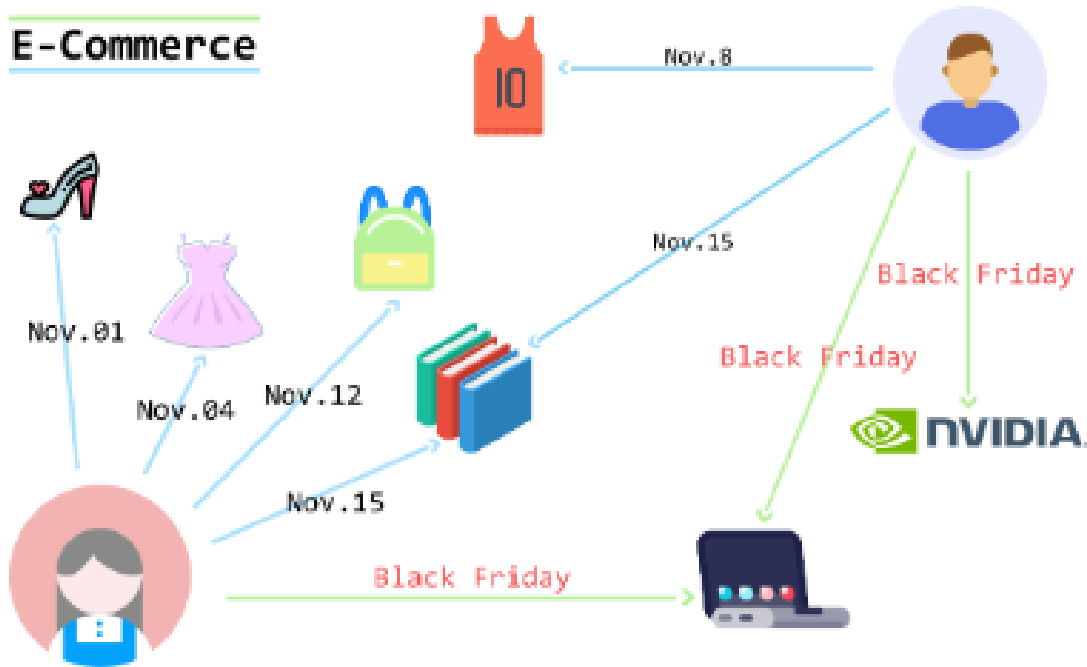

An illustration of user-item graph
An illustration of social graph

➢ **Problem**: Learning dynamic node representations

➢ **Challenges**:

  ➢ Time-varying graph structures: Links and node can emerge and disappear; communities are changing all the time

  ▪ Require the node representations capture both structural proximity (as in static cases) and their temporal evolution

  ▪ Time intervals of events are uneven

  ➢ Causes of the change: can come from different aspects, e.g.in co-authorship network, research community & career stage perspectives
  ▪ Require modeling multi-faceted variations

네트워크 과학 연구실
NETWORK SCIENCE LAB
가톨릭대학교
THE CATHOLIC UNIVERSITY OF KOREA

- ➢ **2 ways to model dynamic**: Discrete model and continuous model

  - ➢ Discrete model: Sequence of network snapshots within a given time interval

    - ▪ $G = \{G_1, \ldots, G_T\}$, where T is the number of snapshots. Each snapshot $G_t = (V_t, E_t)$ is a static network recorded at time t

  - ➢ Continuous model: a network with edges and nodes annotated with timestamps

    - ▪ We have $G = (V_T, E_T, \Im)$, where $\Im : V, E \rightarrow \mathbb{R}^+$ is a function that maps each edge and node to a corresponding timestamp

Timestamps	
Edges	Vertices
a-t1	1-t1
b-t3	2-t1
c-t3	3-t2
d-t4	4-t3
e-t5	5-t5
f-t6	6-t5

Zhiping Xiao:"Dynamic Graph Representation Learning."

네트워크 과학 연구실 NETWORK SCIENCE LAB 가톨릭대학교 THE CATHOLIC UNIVERSITY OF KOREA

➢ **Motivation**: Networks in the real world are always evolving

  ➢ New users (new nodes) in social networks, new citations (new edges) in citation networks

  ➢ Users may delete friends (delete edges) or some users may leave the network (delete nodes)

➢ The static graph embedding methods are not capable of dealing with the critical challenge involved in dynamic networks

  ➢ **Disadvantage**: embedding vectors for each timestamp are in different spaces

    ▪ Lead to learn embedding vectors separately is a time-consuming process

➢ **Solution**: dynnode2vec method to modify the node2vec method

  ➢ Employ the previous learned embedding vectors as initials weights for the skip-gram model

Sedigheh Mahdavi et al:"dynnode2vec: Scalable Dynamic Network Embedding."
- ➢ Given a dynamic graph as a sequence $G_1, G_2, \ldots, G_T$ from timestamp 1 to T

- ➢ Each graph at time t is defined as $G_t = (V_t, E_t)$

- ➢ **Evolving Random Walk Generation:**

  - ➢ Only generates random walks for the set of "evolving nodes" (ΔV_t) that have changed between consecutive timestamps t and t+1:

  $$\Delta V_t = V_{add} \cup \{v_i \in V_t | \exists e_i = (v_i, v_j) \in (E_{add} \cup E_{del})\}$$

    - ▪ Change: New nodes added, existing nodes deleted, or edges added/removed for existing nodes)

- ➢ Dynamic Skip-gram Model:

  - ➢ Initialize the skip-gram model at timestamp t with the pre-trained embedding vectors from the previous timestamp t-1.

  - ➢ Vocabulary is updated based on the new evolving random walks, and Skip-gram t is retrained using only the new evolving random walks on the evolving node set ΔV_t

➢ Run static node2vec on the initial graph G_1 to get embedding vectors Z_1

➢ For each subsequent timestamp t=2 to T:

   a) Find evolving node set ΔV_t

   b) Sample new random walks only for ΔV_t

   c) Train Skip-gram using new walks, initialized with Skip-gram t-1

   d) Obtain embedding vectors Z_t

Algorithm 1 :Algorithm: Dynnode2vec

1: **Input**: Graphs $G = G_1, G_2, \ldots, G_T$
2: **Output**: Embedding vectors $Z_1, Z_2, \ldots, Z_T$
3: Run static *node2vec* for the Graph G_1
4: **for** $t = 2$ to N **do**
5:     Find a set of evolving nodes,ΔV_t,
6:     Sample new random walks $(Walk_n)$ for ΔV_t
7:     Train Skip-Gram $Skip_t$ with $Walk_n$ and obtain Z_t
8: **end for**

Sedigheh Mahdavi et al:"dynnode2vec: Scalable Dynamic Network Embedding."

네트워크 과학 연구실 NETWORK SCIENCE LAB   가톨릭대학교 THE CATHOLIC UNIVERSITY OF KOREA

➢ **Motivation**: Traditional methods often treat dynamic network as a sequence of static snapshots, which loss important temporal information

➢ **Solution**: Treat network as a continuous-time dynamic network, capturing the exact times of interaction
➢ A continuous-time dynamic network is defined as $G = (V, E_T, \Im)$

  ➢ V: set of nodes

  ➢ $E_T \subseteq V \times V \times R^+$: set of temporal edges between vertices in V

  ➢ $\Im: E \to R^+$: a function that maps each edge to a corresponding timestamp

➢ Temporal walk:

  ➢ A temporal walk from v_1 to v_k in G is a sequence of nodes $\langle v_1, v_2, \dots, v_k \rangle$ such that

    ➢ $\langle v_i, v_{i+1} \rangle$ for $1 \leq i < k$ and

    ➢ $\Im(v_i, v_{i+1}) \leq \Im(v_{i+1}, v_{i+2})$ for $1 \leq i < (k-1)$
➢ **Temporal random walk**:

➢ The set of temporal neighbors of a node v at time t:

$$\Gamma_t(v) = \{(w, t') \mid e = (v, w, t') \in E_T \ \wedge \ \mathcal{T}(e) > t\}$$

➢ Unbiased selection: each temporal neighbor w of node v at time t is selected

$$\Pr(w) = 1/|\Gamma_t(v)|$$

➢ Biased selection: sampling the next node in a temporal walk via temporally weighted distribution based on

$$\Pr(w) = \frac{\exp\left[\tau(w) - \tau(v)\right]}{\sum_{w' \in \Gamma_t(v)} \exp\left[\tau(w') - \tau(v)\right]}$$

Exponential decay: selecting a neighbor decreases exponentially with time

$$\Pr(w) = \frac{\delta(w)}{\sum_{w' \in \Gamma_t(v)} \delta(w')}$$

Linear decay: sorts temporal neighbors in descending order time-wise.

➢ Temporal context windows: To handle the temporal nature of walks - a walk to run out of temporally valid edges to traverse

  ➢ A walk must have a minimum length ω and can extend up to a maximum length L

  ➢ The number of context windows is defined

$$\beta = \sum_{i=1}^{k} |S_{t_i}| - \omega + 1$$

➢ Learning time-preserving embeddings: maximize the likelihood of observing temporal context windows given the embeddings

$$\max_{f} \log \Pr \left(W_T = \{v_{i-\omega}, \cdots, v_{i+\omega}\} \setminus v_i \mid f(v_i) \right)$$

➡ Utilizing stochastic gradient descent

Algorithm 1 Continuous-Time Dynamic Network Embeddings

Input:

a (un)weighted and (un)directed dynamic network $G = (V, E_T, \mathcal{T})$,

temporal context window count β, context window size ω,

embedding dimensions D,

1   Set maximum walk length $L = 80$

2   Initialize set of *temporal walks* $\mathcal{S}_T$ to $\emptyset$

3   Initialize number of context windows $C = 0$

4   Precompute sampling distribution $\mathbb{F}_s$ using G

      $\mathbb{F}_s \in \{\text{Uniform, Exponential, Linear}\}$

5   $G' = (V, E_T, \mathcal{T}, \mathbb{F}_s)$

6   **while** $\beta - C > 0$ **do**

7   Sample an edge $e_* = (v, u)$ via distribution $\mathbb{F}_s$

8      $t = \mathcal{T}(e_*)$

9      $S_t = \text{TEMPORALWALK}(G', e_* = (v, u), t, L, \omega + \beta - C - 1)$

10   **if** $|S_t| > \omega$ **then**

11   Add the *temporal walk* S_t to $\mathcal{S}_T$

12        $C = C + (|S_t| - \omega + 1)$

13   **end while**

14   $Z = \text{STOCHASTICGRADIENTDESCENT}(\omega, D, \mathcal{S}_T)$

15   **return** the *dynamic* node embedding matrix Z
Algorithm 2 Temporal Random Walk

1   **procedure** TEMPORALWALK(G', $e = (s, r)$, t, L, C)

2   Initialize temporal walk $S_t = [\, s, r \,]$

3   Set $i = r$ ▷ current node

4   **for** $p = 1$ **to** $min(L, C) - 1$ **do**

5       $\Gamma_t(i) = \{(w, t') \mid e = (i, w, t') \in E_T \wedge \mathcal{T}(i) > t\}$

6   **if** $|\Gamma_t(i)| > 0$ **then**

7   Select node j from distribution $\mathbb{F}_\Gamma(\Gamma_t(i))$

8   Append j to S_t

9   Set $t = \mathcal{T}(i, j)$

10   Set $i = j$

11   **else** terminate temporal walk

12   **return** temporal walk S_t of length $|S_t|$ rooted at node s

➢ Initialize parameters and precompute sampling distributions

➢ Sample temporal walks using the specified distributions

➢ Use stochastic gradient descent to optimize the embeddings
